WHAT INFORMATION DOES A LOG CONTAIN?

Logs typically contain a variety of information depending on the type of log and the specific event or activity being recorded. However, some common elements found in most logs include:

Timestamp: The date and time when the event occurred. This helps in establishing a chronological sequence of events.

Event Type/Severity Level: Indicates the nature or severity of the event, such as informational, warning, error, or critical.

Event Source/Component: Identifies the source or component within the system or application that generated the event. It could be the name of an application, system process, or device.

Outcome/Result: Indicates the outcome or result of the event, such as success, failure, completion, or termination.

IP Address/Host: Specifies the IP address, hostname, or network identifier associated with the event, especially relevant for network-related events.

Event Description/Message: Provides a brief description or message explaining the event, including relevant details such as error codes, status messages, or actions taken.

User/Actor: Specifies the user or entity associated with the event, such as a username, user ID, or system service account.

Resource/Target: Identifies the resource, object, or system component affected by the event, such as a file, database record, network device, or application module.

Session/Transaction ID: Provides a unique identifier for the session or transaction associated with the event, facilitating correlation and tracking across multiple logs.

Additional Contextual Data: May include additional contextual information relevant to the event, such as location, device type, operating system, browser version, or error stack trace.
